

# Coronavirus lingers in rooms and toilets, but disinfectants kill it

Washington (AFP)

New research from Singapore published Wednesday showed that patients with the novel coronavirus extensively contaminate their bedrooms and bathrooms, underscoring the need to routinely clean high-touch surfaces, basins and toilet bowls.

On the other hand, the virus was killed by twice-a-day cleaning of surfaces and daily cleaning of floors with a commonly used disinfectant, which suggests that current decontamination measures are sufficient as long as people adhere to them.

The research letter was published in the Journal of the American Medical Association (JAMA) and comes after cases in China where the pathogen spread extensively through hospitals, infecting dozens of health care workers and other patients.

This led scientists to believe that, beyond catching the infection through coughing, environmental contamination was an important factor in the disease's transmission, but its extent was unclear.

Researchers at Singapore's National Centre for Infectious Diseases and DSO National Laboratories looked at the cases of three patients who were held in isolation rooms between late January and early February.

They collected samples from their rooms on five days over a two-week period.

The room of one patient was sampled before routine cleaning, while the rooms of the other two patients were sampled after disinfection measures.

The patient whose room was sampled before cleaning had the mildest symptoms of the three, only experiencing a cough. The other two had moderate symptoms: both had coughing and fever, one experienced shortness of breath and the other was coughing up lung mucus.

Despite this disparity, the patient whose room was sampled before cleaning contaminated 13 of 15 room sites testing, including their chair, bed rail, the glass window of their room, the floor, light switches.

Three of the five toilet sites were also contaminated, including the sink, door handle and toilet bowl -- more evidence that stool can be a route of transmission.

Air samples tested negative, but swabs taken from air exhaust outlets were positive -- which suggests that virus-laden droplets may be carried by air flows and deposited on vents.

"Significant environmental contamination by patients with SARS-CoV-2 through respiratory droplets and fecal shedding suggests the environment as a potential medium of transmission and supports the need for strict adherence to environmental and hand hygiene," the authors wrote.

SARS-CoV-2 is the official name of the pathogen.

The virus, which was first identified in China's Hubei province in December has now infected more than 95,000 people in 81 countries and territories, killing more than 3,200.

The World Health Organization said Wednesday the mortality rate was 3.4 percent, revising upward previous estimates.
